# **Chapter 1: Introduction**

## **Computer System Overview**

- A computer system consists of HW& SW that are combined to provide a tool to solve specific problems
  - Application SW.: a tool to solve specific problem
  - System SW.: a general environment to create specific application
  - General shape of the system

- An OS is a program which acts as an *interface* between computer system users and the computer hardware.
- It provides a user-friendly environment in which a user may easily develop and execute programs.
- Otherwise, hardware knowledge would be mandatory for computer programming.
- So, it can be said that an OS hides the complexity of hardware from uninterested users.

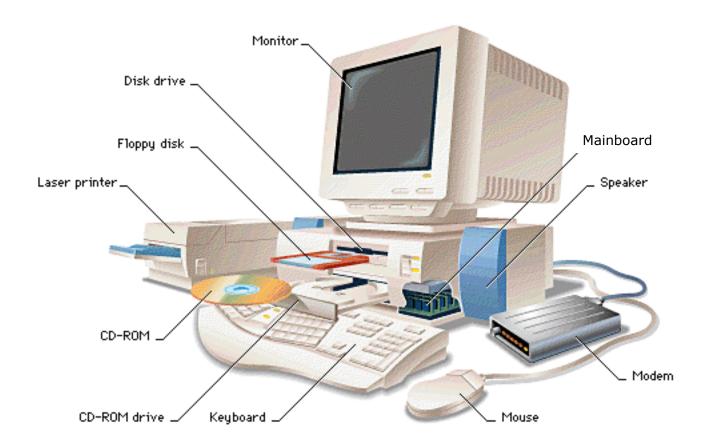

- In general, a computer system has some resources which may be utilized to solve a problem. They are
  - Memory
  - Processor(s)
  - I/O
  - File System
  - etc.

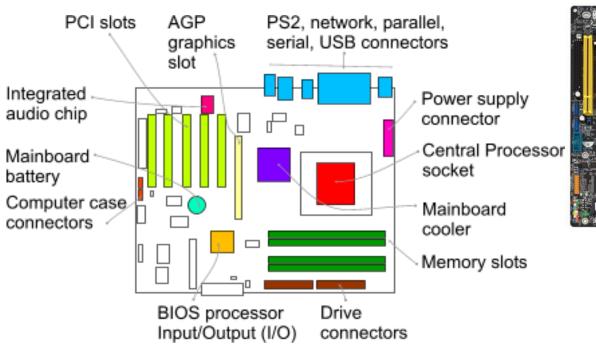

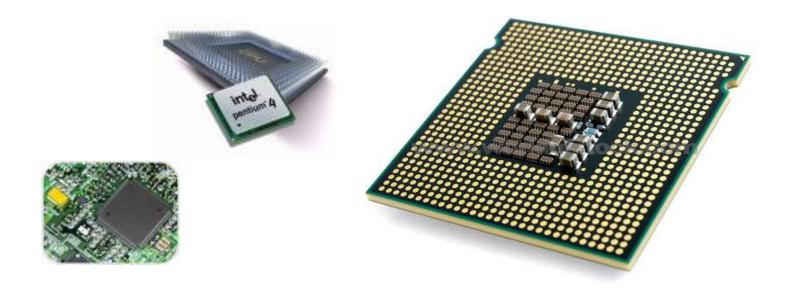

mainboard

processor

**RAM** 

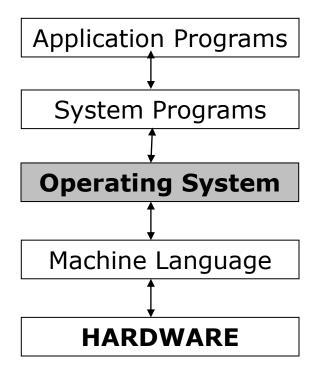

- The OS manages these resources and allocates them to specific programs and users.
- With the management of the OS, a programmer is rid of difficult hardware considerations.
- An OS provides services for
  - Processor Management
  - Memory Management
  - File Management
  - Device Management
  - Concurrency Control

- Another aspect for the usage of OS is that; it is used as a *predefined library* for hardware-software interaction.
- This is why, system programs apply to the installed OS since they cannot reach hardware directly.

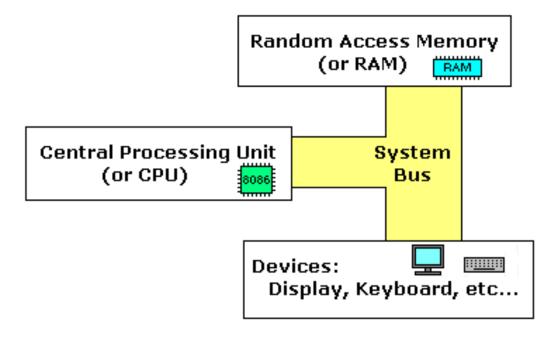

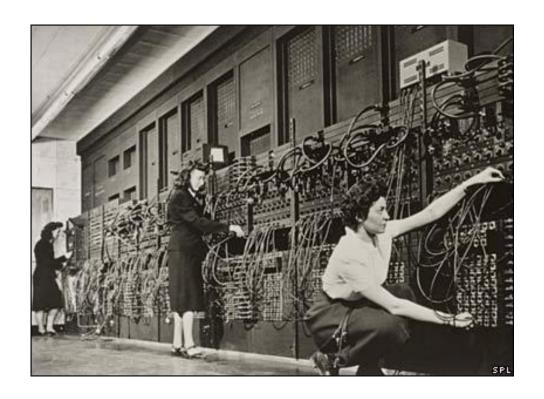

#### **Hardware**

- Hardware resources
  - Processor
  - Memory
  - I/O controller

It all started with computer hardware in about 1940s.

**ENIAC 1943** 

- ENIAC (Electronic Numerical Integrator and Computer), at the U.S. Army's Aberdeen Proving Ground in Maryland.
  - built in the 1940s,
  - weighed 30 tons,
  - was eight feet high, three feet deep, and 100 feet long
  - contained over 18,000 vacuum tubes that were cooled by 80 air blowers.

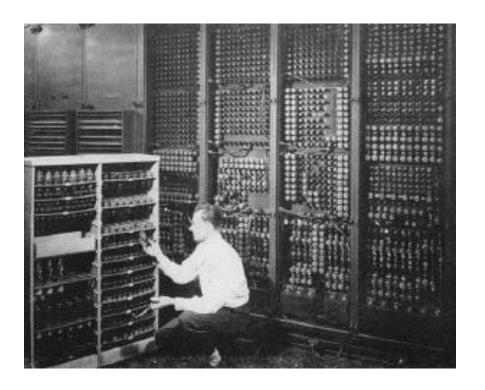

Computers were using vacuum tube technology.

ENIAC's vacuum tubes

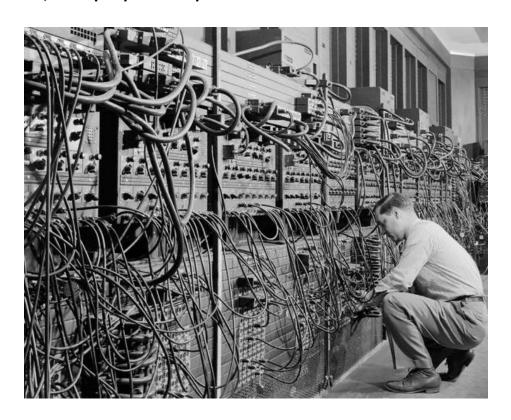

ENIAC's backside

Programs were loaded into memory manually using switches, punched cards, or paper tapes.

ENIAC: coding by cable connections

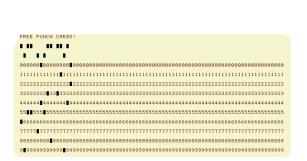

#### punch card

```
EREE PUNCH CARDS!
```

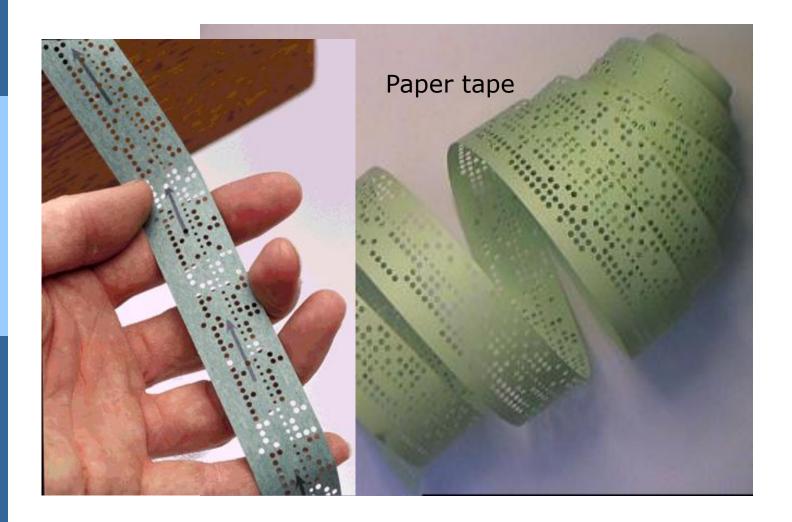

# 1

# 1.2 History of Operating Systems

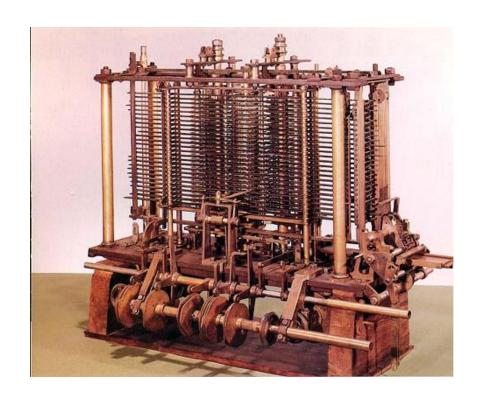

Punched Paper Tape 25.4 mm wide. Ascii 7-bit character code. Even Parity.

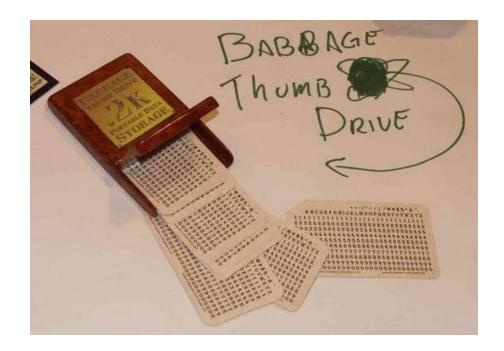

Babbage's analytical engine (designed in 1840's by Charles Babbage, but cold not be constructed by him.

An earlier and simpler version is constructed in 2002, in London

 Ada Lovalence (at time of Charles Babbage) wrote code for analytical engine to compute Bernulli Numbers

Operating systems have been evolving through the years. Following table shows the history of OS.

Generation	Year	Electronic devices	Types of OS and
		used	devices
First	1945 – 55	Vacuum tubes	Plug boards
Second	1955 – 1965	Transistors	Batch system
Third	1965 – 1980	Integrated Circuit (IC)	Multiprogramming
Fourth	Since 1980	Large scale integration	PC

- As time went on, card readers, printers, and magnetic tape units were developed as additional hardware elements.
- Assemblers, loaders and simple utility libraries were developed as software tools.
- Later, off-line spooling and channel program methods were developed sequentially.

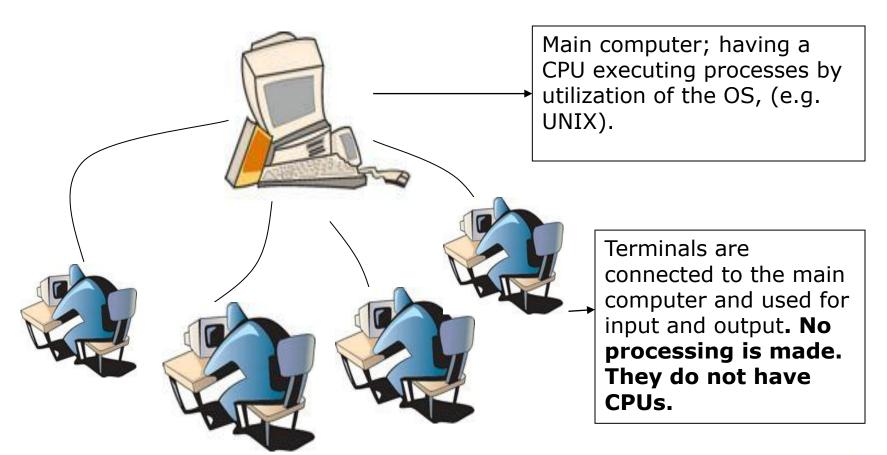

- Finally, the idea of **multiprogramming** came.
- Multiprogramming means sharing of resources between more than one processes.
- By multiprogramming the CPU time is not wasted, because, while one process moves on some I/O work, the OS picks another process to execute till the current one passes to I/O operation.

- With the development of interactive computation in 1970s, time-sharing systems emerged.
- In these systems, multiple users have *terminals* (not computers) connected to a *main computer* and execute her task in the main computer.

- Another computer system is the multiprocessor system having multiple processors sharing memory and peripheral devices.
- With this configuration, they have greater computing power and higher reliability.

- Multiprocessor systems are classified into two as tightlycoupled and loosely-coupled (distributed).
- In the tightly-coupled one, <u>each processor is</u> <u>assigned a specific duty</u> but processors work in close association, possibly sharing the same memory.
- In the loosely coupled one, each processor has its own memory and copy of the OS.

## What is an Operating System?

- A program that acts as an intermediary between a user of a computer and the computer hardware
- Operating system goals:
  - Execute user programs and make solving user problems easier
  - Make the computer system convenient to use
  - Use the computer hardware in an efficient manner

### What is an Operating System?

- Os is designed to serve two basic purposes:
  - It controls the allocation and use of computing systems resources among the various user and tasks
  - Provides interface between the computer hardware and the programmer that simplifies and makes feasible for Coding, creating, debugging of application programs

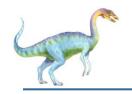

### What is an Operating System?

- The operating system must support the following tasks:
  - 1. Provides the facilities to create, modification of program and data file using and editor
  - Access the complier for translating the user program from high level language to machine language
  - Provides loader program to move the complied program code to the computers memory for execution
  - 4. Provide routines that handle details of I/o programming

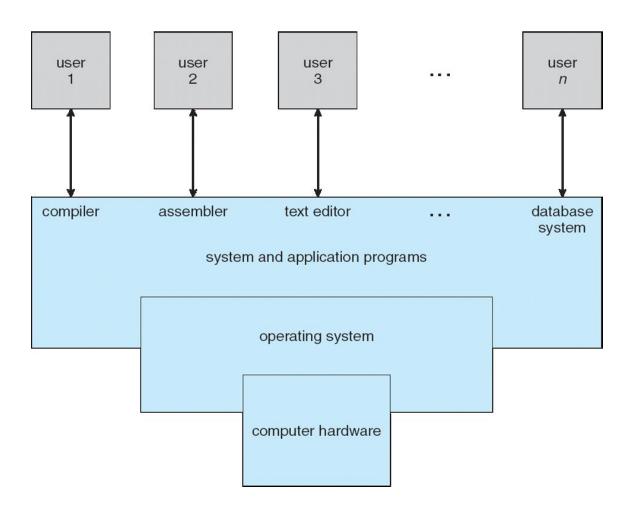

### **Computer System Structure**

- Computer system can be divided into four components:
  - Hardware provides basic computing resources
    - ▶ CPU, memory, I/O devices
  - Operating system
    - Controls and coordinates use of hardware among various applications and users
  - Application programs define the ways in which the system resources are used to solve the computing problems of the users
    - Word processors, compilers, web browsers, database systems, video games
  - Users
    - People, machines, other computers

### Four Components of a Computer System

## **What Operating Systems Do**

- Depends on the point of view
- Users want convenience, ease of use and good performance
  - Don't care about resource utilization
- But shared computer such as mainframe or minicomputer must keep all users happy
- Users of dedicate systems such as workstations have dedicated resources but frequently use shared resources from servers
- Handheld computers are resource poor, optimized for usability and battery life
- Some computers have little or no user interface, such as embedded computers in devices and automobiles

# **Operating System Definition**

- OS is a resource allocator
  - Manages all resources
  - Decides between conflicting requests for efficient and fair resource use
- OS is a control program
  - Controls execution of programs to prevent errors and improper use of the computer

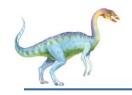

# **Operating System Definition (Cont.)**

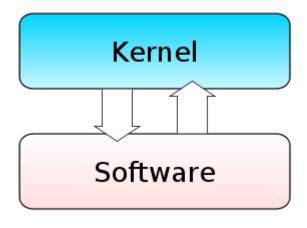

- No universally accepted definition
- "Everything a vendor ships when you order an operating system" is a good approximation
  - But varies wildly
- Kernal "The one program running at all times on the computer" is the kernel.
- Shell: is a program that takes your commands from the keyboard and gives them to the operating system to perform.
  - In the old days, it was the only user interface available on a Unix computer.
  - Nowadays, we have graphical user interfaces (GUIs) in addition to command line interfaces (CLIs) such as the shell. Example(DIR dos)
- Everything else is either
  - a system program (ships with the operating system), or
  - an application program.

# **Computer Startup**

- bootstrap program is loaded at power-up or reboot
  - Typically stored in ROM or EPROM, generally known as firmware
    - permanent software programmed into a read-only memory.
  - Initializes all aspects of system
  - Loads operating system kernel and starts execution

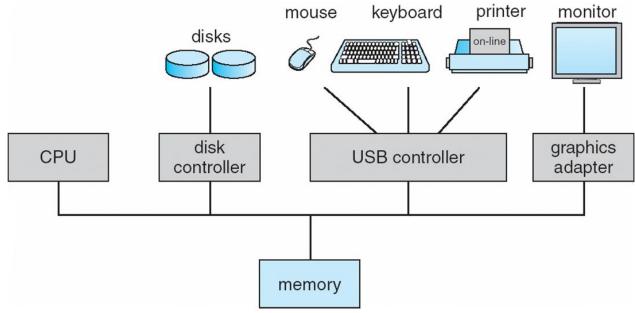

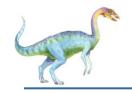

# **Computer System Organization**

- Computer-system operation
  - One or more CPUs, device controllers connect through common bus providing access to shared memory
  - Concurrent execution of CPUs and devices competing for memory cycles

# **Computer-System Operation**

- I/O devices and the CPU can execute concurrently
- Each device controller is in charge of a particular device type
- Each device controller has a local buffer
- CPU moves data from/to main memory to/from local buffers
- I/O is from the device to local buffer of controller
- Device controller informs CPU that it has finished its operation by causing an interrupt

# **Common Functions of Interrupts**

- Interrupt transfers control to the interrupt service routine generally, through the interrupt vector, which contains the addresses of all the service routines
- Interrupt architecture must save the address of the interrupted instruction
- A trap or exception is a software-generated interrupt caused either by an error or a user request
- An operating system is interrupt driven

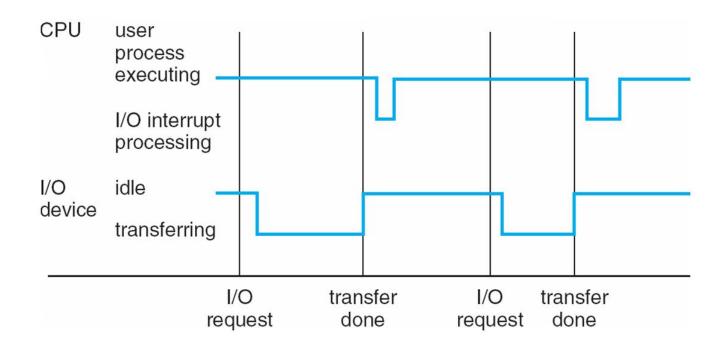

# **Interrupt Handling**

- The operating system preserves the state of the CPU by storing registers and the program counter
- Determines which type of interrupt has occurred:
  - Polling (select what action will be executed)
  - vectored interrupt system
- Separate segments of code determine what action should be taken for each type of interrupt

# **Interrupt Timeline**

#### I/O Structure

- After I/O starts, control returns to user program only upon I/O completion
  - Wait instruction idles the CPU until the next interrupt
  - Wait loop (contention for memory access)
  - At most one I/O request is outstanding at a time, no simultaneous I/O processing
- After I/O starts, control returns to user program without waiting for I/O completion
  - System call request to the OS to allow user to wait for I/O completion
  - Device-status table contains entry for each I/O device indicating its type, address, and state
  - OS indexes into I/O device table to determine device status and to modify table entry to include interrupt

### **Storage Definitions and Notation Review**

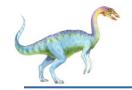

The basic unit of computer storage is the **bit**. A bit can contain one of two values, 0 and 1. All other storage in a computer is based on collections of bits. Given enough bits, it is amazing how many things a computer can represent: numbers, letters, images, movies, sounds, documents, and programs, to name a few. A **byte** is 8 bits, and on most computers it is the smallest convenient chunk of storage. For example, most computers don't have an instruction to move a bit but do have one to move a byte. A less common term is **word**, which is a given computer architecture's native unit of data. A word is made up of one or more bytes. For example, a computer that has 64-bit registers and 64-bit memory addressing typically has 64-bit (8-byte) words. A computer executes many operations in its native word size rather than a byte at a time.

Computer storage, along with most computer throughput, is generally measured and manipulated in bytes and collections of bytes.

A **kilobyte**, or **KB**, is 1,024 bytes

- a **megabyte**, or **MB**, is 1,024<sup>2</sup> bytes
- a **gigabyte**, or **GB**, is 1,024<sup>3</sup> bytes
- a **terabyte**, or **TB**, is 1,024<sup>4</sup> bytes
- a **petabyte**, or **PB**, is 1,024<sup>5</sup> bytes

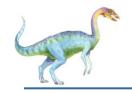

Computer manufacturers often round off these numbers and say that a megabyte is 1 million bytes and a gigabyte is 1 billion bytes. Networking measurements are an exception to this general rule; they are given in bits (because networks move data a bit at a time).

# **Storage Structure**

- Main memory only large storage media that the CPU can access directly
  - Random access
  - Typically volatile (Data is lost when power off)
- Secondary storage extension of main memory that provides large nonvolatile storage capacity
- Hard disks rigid metal or glass platters covered with magnetic recording material
  - Disk surface is logically divided into tracks, which are subdivided into sectors
  - The disk controller determines the logical interaction between the device and the computer
- Solid-state disks faster than hard disks, nonvolatile
  - Various technologies
  - Becoming more popular

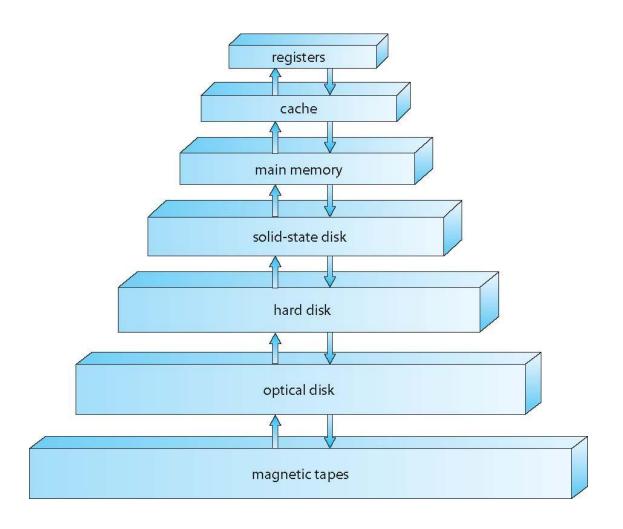

# **Storage Hierarchy**

- Storage systems organized in hierarchy
  - Speed
  - Cost
  - Volatility
- Caching copying information into faster storage system; main memory can be viewed as a cache for secondary storage
- Device Driver for each device controller to manage I/O
  - Provides uniform interface between controller and kernel

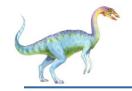

# **Storage-Device Hierarchy**

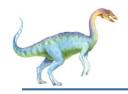

# Caching

- Important principle, performed at many levels in a computer (in hardware, operating system, software)
- Information in use copied from slower to faster storage temporarily
- Faster storage (cache) checked first to determine if information is there
  - If it is, information used directly from the cache (fast)
  - If not, data copied to cache and used there
- Cache smaller than storage being cached
  - Cache management important design problem
  - Cache size and replacement policy

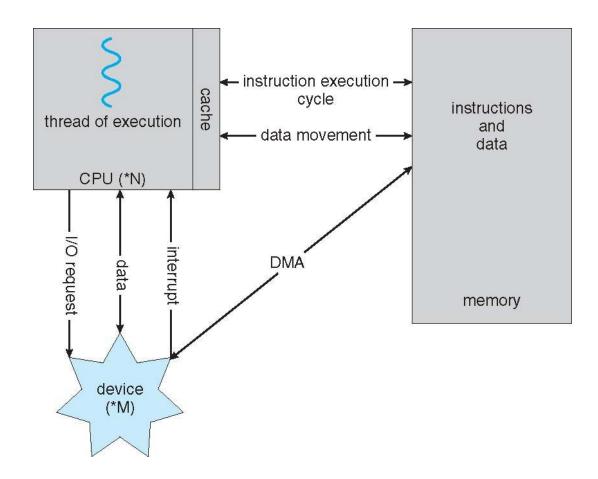

# **Direct Memory Access Structure**

- Used for high-speed I/O devices able to transmit information at close to memory speeds
- Device controller transfers blocks of data from buffer storage directly to main memory without CPU intervention
- Only one interrupt is generated per block, rather than the one interrupt per byte

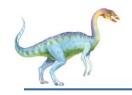

# **How a Modern Computer Works**

A von Neumann architecture

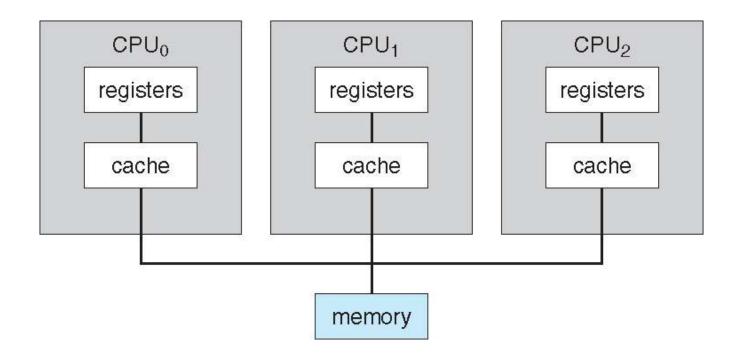

# **Computer-System Architecture**

- Most systems use a single general-purpose processor
  - Most systems have special-purpose processors as well
- Multiprocessors systems growing in use and importance
  - Also known as parallel systems, tightly-coupled systems
  - Advantages include:
    - 1. Increased throughput
    - 2. Economy of scale
    - 3. Increased reliability graceful degradation or fault tolerance
  - Two types:
    - Asymmetric Multiprocessing each processor is assigned a specie task.
    - 2. Symmetric Multiprocessing each processor performs all tasks

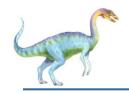

## **Symmetric Multiprocessing Architecture**

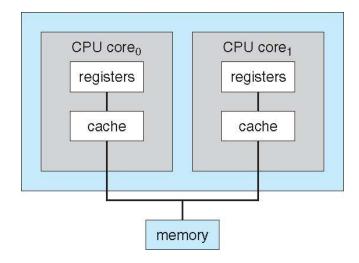

# A Dual-Core Design

- Multi-chip and multicore
- Systems containing all chips
  - Chassis containing multiple separate systems

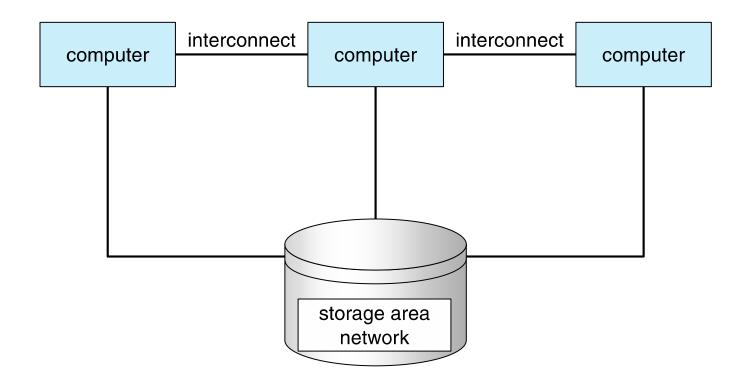

# **Clustered Systems**

- Like multiprocessor systems, but multiple systems working together
  - Usually sharing storage via a storage-area network (SAN)
  - Provides a high-availability service which survives failures
    - Asymmetric clustering has one machine in hot-standby mode
    - Symmetric clustering has multiple nodes running applications, monitoring each other
  - Some clusters are for high-performance computing (HPC)
    - Applications must be written to use parallelization
  - Some have distributed lock manager (DLM) to avoid conflicting operations

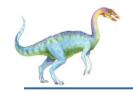

# **Clustered Systems**

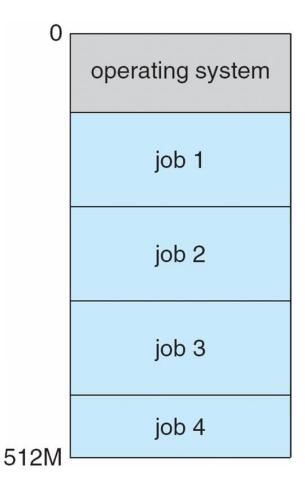

# **Operating System Structure**

- Multiprogramming (Batch system) needed for efficiency
  - Single user cannot keep CPU and I/O devices busy at all times
  - Multiprogramming organizes jobs (code and data) so CPU always has one to execute
  - A subset of total jobs in system is kept in memory
  - One job selected and run via job scheduling
  - When it has to wait (for I/O for example), OS switches to another job
- Timesharing (multitasking) is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating interactive computing
  - Response time should be < 1 second</li>
  - Each user has at least one program executing in memory ⇒process
  - If several jobs ready to run at the same time ⇒ CPU scheduling
  - If processes don't fit in memory, swapping moves them in and out to run
  - Virtual memory allows execution of processes not completely in memory

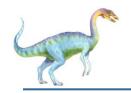

# **Memory Layout for Multiprogrammed System**

# **Operating-System Operations**

- Interrupt driven (hardware and software)
  - Hardware interrupt by one of the devices
  - Software interrupt (exception or trap):
    - Software error (e.g., division by zero)
    - Request for operating system service
    - Other process problems include infinite loop, processes modifying each other or the operating system

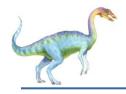

# **Operating-System Operations (cont.)**

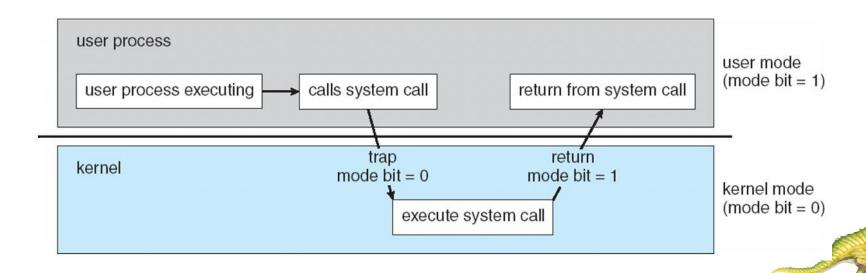

- Dual-mode operation allows OS to protect itself and other system components
  - User mode and kernel mode
  - Mode bit provided by hardware
    - Provides ability to distinguish when system is running user code or kernel code
    - Some instructions designated as privileged, only executable in kernel mode
    - System call changes mode to kernel, return from call resets it to user
- Increasingly CPUs support multi-mode operations
  - i.e. virtual machine manager (VMM) mode for guest VMs

## **Transition from User to Kernel Mode**

- Timer to prevent infinite loop / process hogging resources
  - Timer is set to interrupt the computer after some time period
  - Keep a counter that is decremented by the physical clock.
  - Operating system set the counter (privileged instruction)
  - When counter zero generate an interrupt
  - Set up before scheduling process to regain control or terminate program that exceeds allotted time

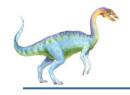

# **Process Management**

- A process is a program in execution. It is a unit of work within the system. Program is a passive entity, process is an active entity.
- Process needs resources to accomplish its task
  - CPU, memory, I/O, files
  - Initialization data
- Process termination requires reclaim of any reusable resources
- Single-threaded process has one program counter specifying location of next instruction to execute
  - Process executes instructions sequentially, one at a time, until completion
- Multi-threaded process has one program counter per thread
- Typically system has many processes, some user, some operating system running concurrently on one or more CPUs
  - Concurrency by multiplexing the CPUs among the processes / threads

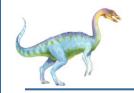

# **Process Management Activities**

The operating system is responsible for the following activities in connection with process management:

- Creating and deleting both user and system processes
- Suspending and resuming processes
- Providing mechanisms for process synchronization
- Providing mechanisms for process communication
- Providing mechanisms for deadlock handling

# **Memory Management**

- To execute a program all (or part) of the instructions must be in memory
- All (or part) of the data that is needed by the program must be in memory.
- Memory management determines what is in memory and when
  - Optimizing CPU utilization and computer response to users
- Memory management activities
  - Keeping track of which parts of memory are currently being used and by whom
  - Deciding which processes (or parts thereof) and data to move into and out of memory
  - Allocating and deallocating memory space as needed

# **Storage Management**

- OS provides uniform, logical view of information storage
  - Abstracts physical properties to logical storage unit file
  - Each medium is controlled by device (i.e., disk drive, tape drive)
    - Varying properties include access speed, capacity, datatransfer rate, access method (sequential or random)
- File-System management
  - Files usually organized into directories
  - Access control on most systems to determine who can access what
  - OS activities include
    - Creating and deleting files and directories
    - Primitives to manipulate files and directories
    - Mapping files onto secondary storage
    - ▶ Backup files onto stable (non-volatile) storage media

# **Mass-Storage Management**

- Usually disks used to store data that does not fit in main memory or data that must be kept for a "long" period of time
- Proper management is of central importance
- Entire speed of computer operation hinges on disk subsystem and its algorithms
- OS activities
  - Free-space management
  - Storage allocation
  - Disk scheduling
- Some storage need not be fast
  - Tertiary storage includes optical storage, magnetic tape
  - Still must be managed by OS or applications
  - Varies between WORM (write-once, read-many-times) and RW (read-write)

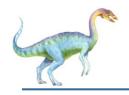

# Performance of Various Levels of Storage

Level	1	2	3	4	5
Name	registers	cache	main memory	solid state disk	magnetic disk
Typical size	< 1 KB	< 16MB	< 64GB	< 1 TB	< 10 TB
Implementation technology	custom memory with multiple ports CMOS	on-chip or off-chip CMOS SRAM	CMOS SRAM	flash memory	magnetic disk
Access time (ns)	0.25 - 0.5	0.5 - 25	80 - 250	25,000 - 50,000	5,000,000
Bandwidth (MB/sec)	20,000 - 100,000	5,000 - 10,000	1,000 - 5,000	500	20 - 150
Managed by	compiler	hardware	operating system	operating system	operating system
Backed by	cache	main memory	disk	disk	disk or tape

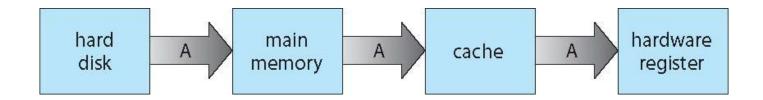

Movement between levels of storage hierarchy can be explicit or implicit

### Migration of data "A" from Disk to Register

 Multitasking environments must be careful to use most recent value, no matter where it is stored in the storage hierarchy

- Multiprocessor environment must provide cache coherency in hardware such that all CPUs have the most recent value in their cache
- Distributed environment situation even more complex
  - Several copies of a datum can exist
  - Various solutions covered in Chapter 17

# I/O Subsystem

- One purpose of OS is to hide peculiarities of hardware devices from the user
- I/O subsystem responsible for
  - Memory management of I/O including buffering (storing data temporarily while it is being transferred), caching (storing parts of data in faster storage for performance), spooling (the overlapping of output of one job with input of other jobs)
  - General device-driver interface
  - Drivers for specific hardware devices

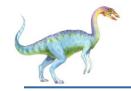

# **Protection and Security**

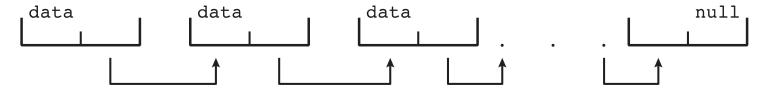

- Protection any mechanism for controlling access of processes or users to resources defined by the OS
- Security defense of the system against internal and external attacks
  - Huge range, including denial-of-service, worms, viruses, identity theft, theft of service
- Systems generally first distinguish among users, to determine who can do what
  - User identities (user IDs, security IDs) include name and associated number, one per user
  - User ID then associated with all files, processes of that user to determine access control
  - Group identifier (group ID) allows set of users to be defined and controls managed, then also associated with each process, file
  - Privilege escalation allows user to change to effective ID with more rights

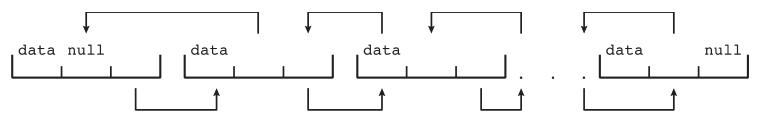

#### **Kernel Data Structures**

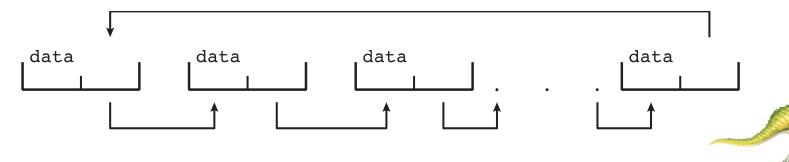

- Many similar to standard programming data structures
- Singly linked list

#### Doubly linked list

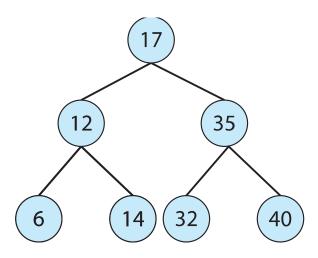

#### Circular linked list

# **Kernel Data Structures**

- Binary search tree
  - left <= right</pre>
    - Search performance is O(n)
    - Balanced binary search tree is O(lg n)

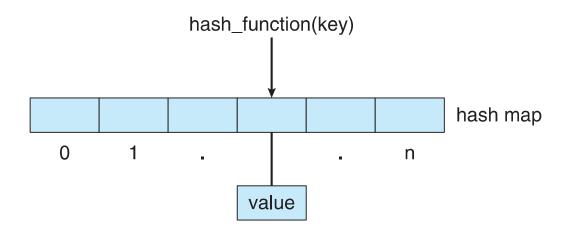

### **Kernel Data Structures**

Hash function can create a hash map

- Bitmap string of *n* binary digits representing the status of *n* items
- Linux data structures defined in

# **Computing Environments - Traditional**

- Stand-alone general purpose machines
- But blurred as most systems interconnect with others (i.e., the Internet)
- Portals provide web access to internal systems
- Network computers (thin clients) are like Web terminals
- Mobile computers interconnect via wireless networks
- Networking becoming ubiquitous even home systems use firewalls to protect home computers from Internet attacks

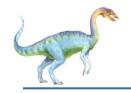

# **Computing Environments - Mobile**

- Handheld smartphones, tablets, etc.
- What is the functional difference between them and a "traditional" laptop?
- Extra feature more OS features (GPS, gyroscope)
- Allows new types of apps like augmented reality
- Use IEEE 802.11 wireless, or cellular data networks for connectivity
- Leaders are Apple iOS and Google Android

# **Computing Environments – Distributed**

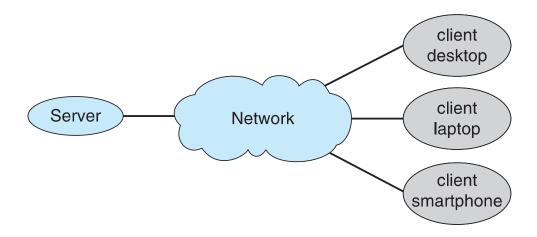

- Distributed computiing
  - Collection of separate, possibly heterogeneous, systems networked together
    - Network is a communications path, TCP/IP most common
      - Local Area Network (LAN)
      - Wide Area Network (WAN)
      - Metropolitan Area Network (MAN)
      - Personal Area Network (PAN)
  - Network Operating System provides features between systems across network
    - Communication scheme allows systems to exchange messages
    - Illusion of a single system

# **Computing Environments – Client-Server**

- Client-Server Computing
  - Dumb terminals supplanted by smart PCs
  - Many systems now servers, responding to requests generated by clients
    - Compute-server system provides an interface to client to request services (i.e., database)
    - File-server system provides interface for clients to store and retrieve files

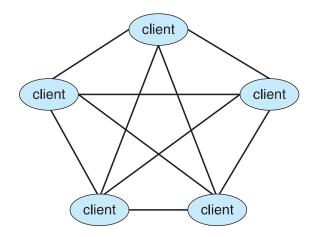

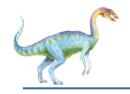

# **Computing Environments - Peer-to-Peer**

- Another model of distributed system
- P2P does not distinguish clients and servers
  - Instead all nodes are considered peers
  - May each act as client, server or both
  - Node must join P2P network
    - Registers its service with central lookup service on network, or
    - Broadcast request for service and respond to requests for service via discovery protocol
  - Examples include Napster and Gnutella,
    Voice over IP (VoIP) such as Skype

# **Computing Environments - Virtualization**

- Allows operating systems to run applications within other OSes
  - Vast and growing industry
- Emulation used when source CPU type different from target type (i.e. PowerPC to Intel x86)
  - Generally slowest method
  - When computer language not compiled to native code Interpretation
- Virtualization OS natively compiled for CPU, running guest
  OSes also natively compiled
  - Consider VMware running WinXP guests, each running applications, all on native WinXP host OS
  - VMM (virtual machine Manager) provides virtualization services

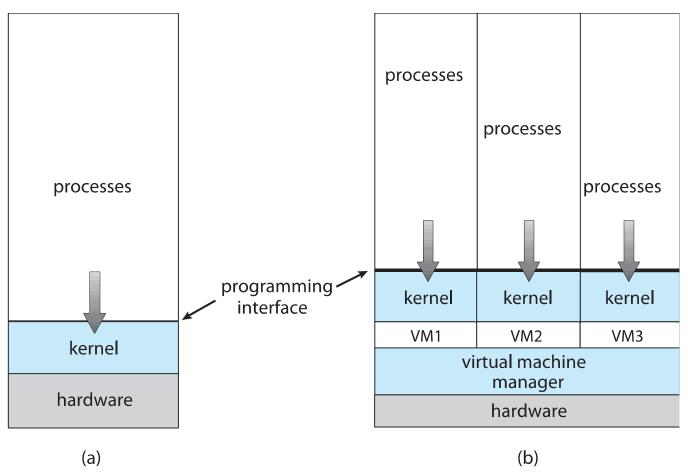

# **Computing Environments - Virtualization**

- Use cases involve laptops and desktops running multiple OSes for exploration or compatibility
  - Apple laptop running Mac OS X host, Windows as a guest
  - Developing apps for multiple OSes without having multiple systems
  - QA testing applications without having multiple systems
  - Executing and managing compute environments within data centers
- VMM can run natively, in which case they are also the host
  - There is no general purpose host then (VMware ESX and Citrix XenServer)

# **Computing Environments - Virtualization**

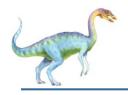

### **Computing Environments – Cloud Computing**

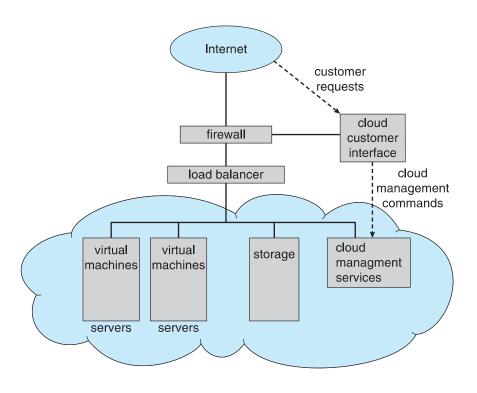

- Delivers computing, storage, even apps as a service across a network
- Logical extension of virtualization because it uses virtualization as the base for it functionality.
  - Amazon EC2 has thousands of servers, millions of virtual machines, petabytes of storage available across the Internet, pay based on usage
- Many types
  - Public cloud available via Internet to anyone willing to pay
  - Private cloud run by a company for the company's own use
  - **Hybrid cloud** includes both public and private cloud components
  - Software as a Service (SaaS) one or more applications available via the Internet (i.e., word processor)
  - Platform as a Service (PaaS) software stack ready for application use via the Internet (i.e., a database server)
  - Infrastructure as a Service (laas) servers or storage available over Internet (i.e., storage available for backup use)

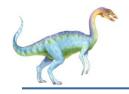

### **Computing Environments – Cloud Computing**

- Cloud computing environments composed of traditional OSes, plus VMMs, plus cloud management tools
  - Internet connectivity requires security like firewalls
  - Load balancers spread traffic across multiple applications

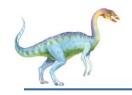

#### **Computing Environments – Real-Time Embedded Systems**

- Real-time embedded systems most prevalent form of computers
  - Vary considerable, special purpose, limited purpose OS, real-time OS
  - Use expanding
- Many other special computing environments as well
  - Some have OSes, some perform tasks without an OS
- Real-time OS has well-defined fixed time constraints
  - Processing *must* be done within constraint
  - Correct operation only if constraints met

# **Open-Source Operating Systems**

- Operating systems made available in source-code format rather than just binary closed-source
- Counter to the copy protection and Digital Rights
  Management (DRM) movement
- Started by Free Software Foundation (FSF), which has "copyleft" GNU Public License (GPL)
- Examples include GNU/Linux and BSD UNIX (including core of Mac OS X), and many more
- Can use VMM like VMware Player (Free on Windows), Virtualbox (open source and free on many platforms http://www.virtualbox.com)
  - Use to run guest operating systems for exploration

# **End of Chapter 1**
